

## Internet of Things (IoT)

- Internet of things (IoT) is an emerging technology where different machines are embedded with sensors to capture and relay data to each other
- Mackenzie Health (MH) implemented IoT in an acute medical unit to test and evaluate new technologies to improve care delivery
- The new system includes: smart beds, smart hand hygiene system, wall call stations, dome light indicators, and smart call bell system

**Research Gap:** No evidence produced to confirm the benefits of this intervention

Table 1: Smart Technologies Implemented in MH

|   |                          |   |                               |
|---|--------------------------|---|-------------------------------|
|  | Smart Bed                |  | Smart badge                   |
|  | Blackberry Mobile Phones |  | Dome light indicators         |
|  | Wall Call Station        |  | Hand Hygiene Support Solution |

## Research Questions(RQ)

**RQ1)** What impact of IoT implementation has on quality of care dimensions (efficiency, Patient safety, timeliness):

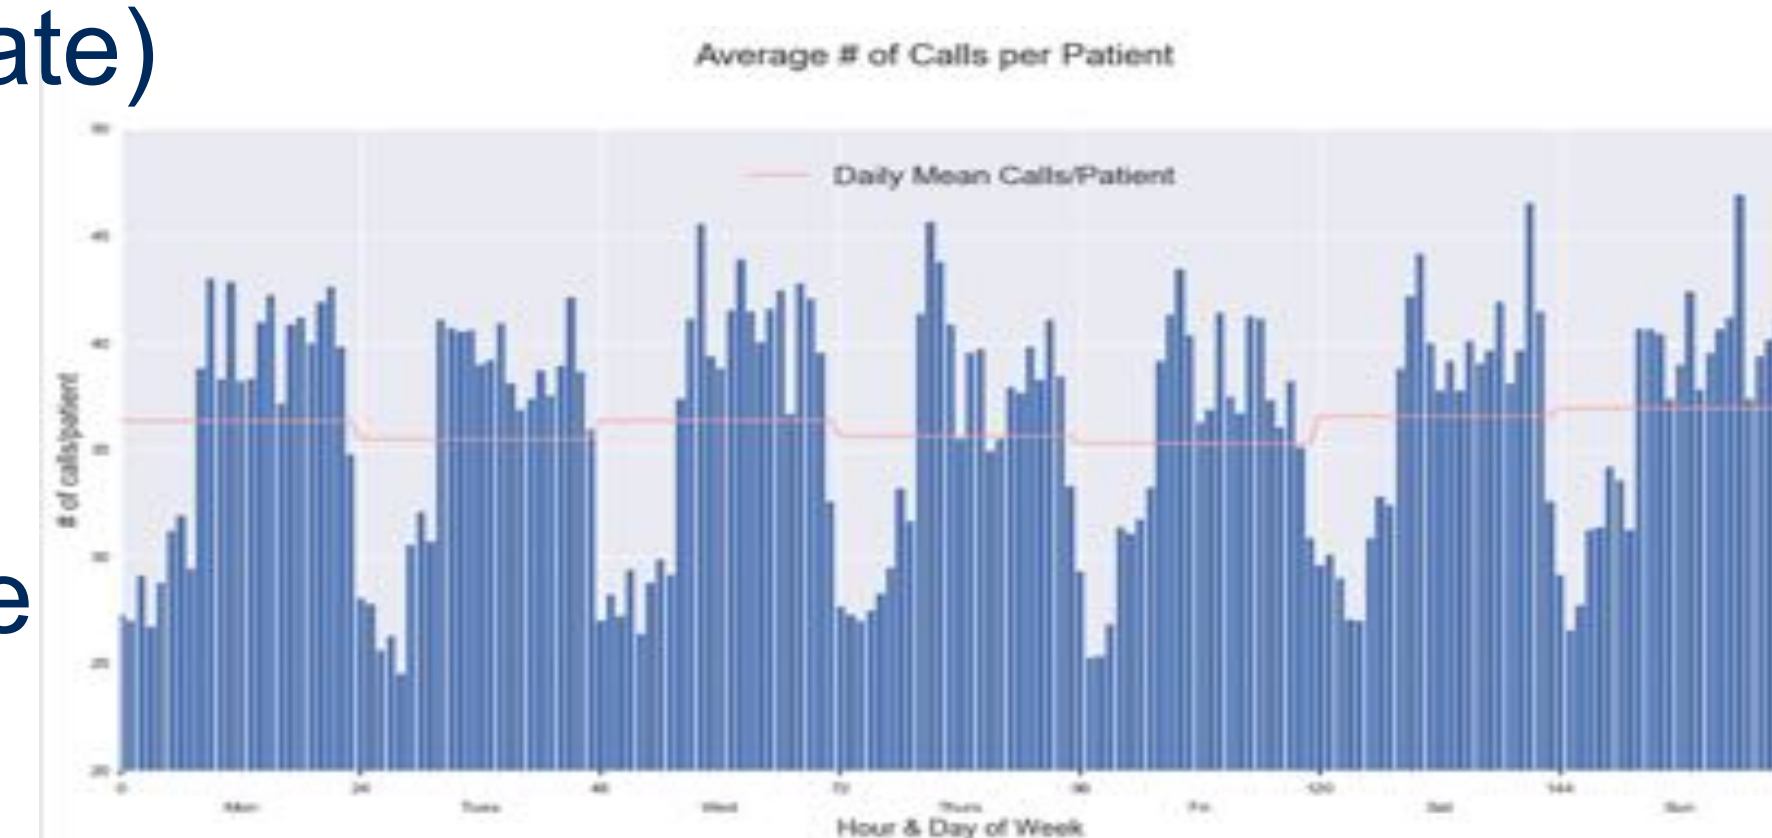

- Patient length of stay?, Patient fall rate?
- Hand-Hygiene(HH) compliance?
- Patient call bell response time?
- Nurse distance travelled per shift?
- Nurse satisfaction?

**RQ2)** How can we further improve the unit operations?

## Methodology

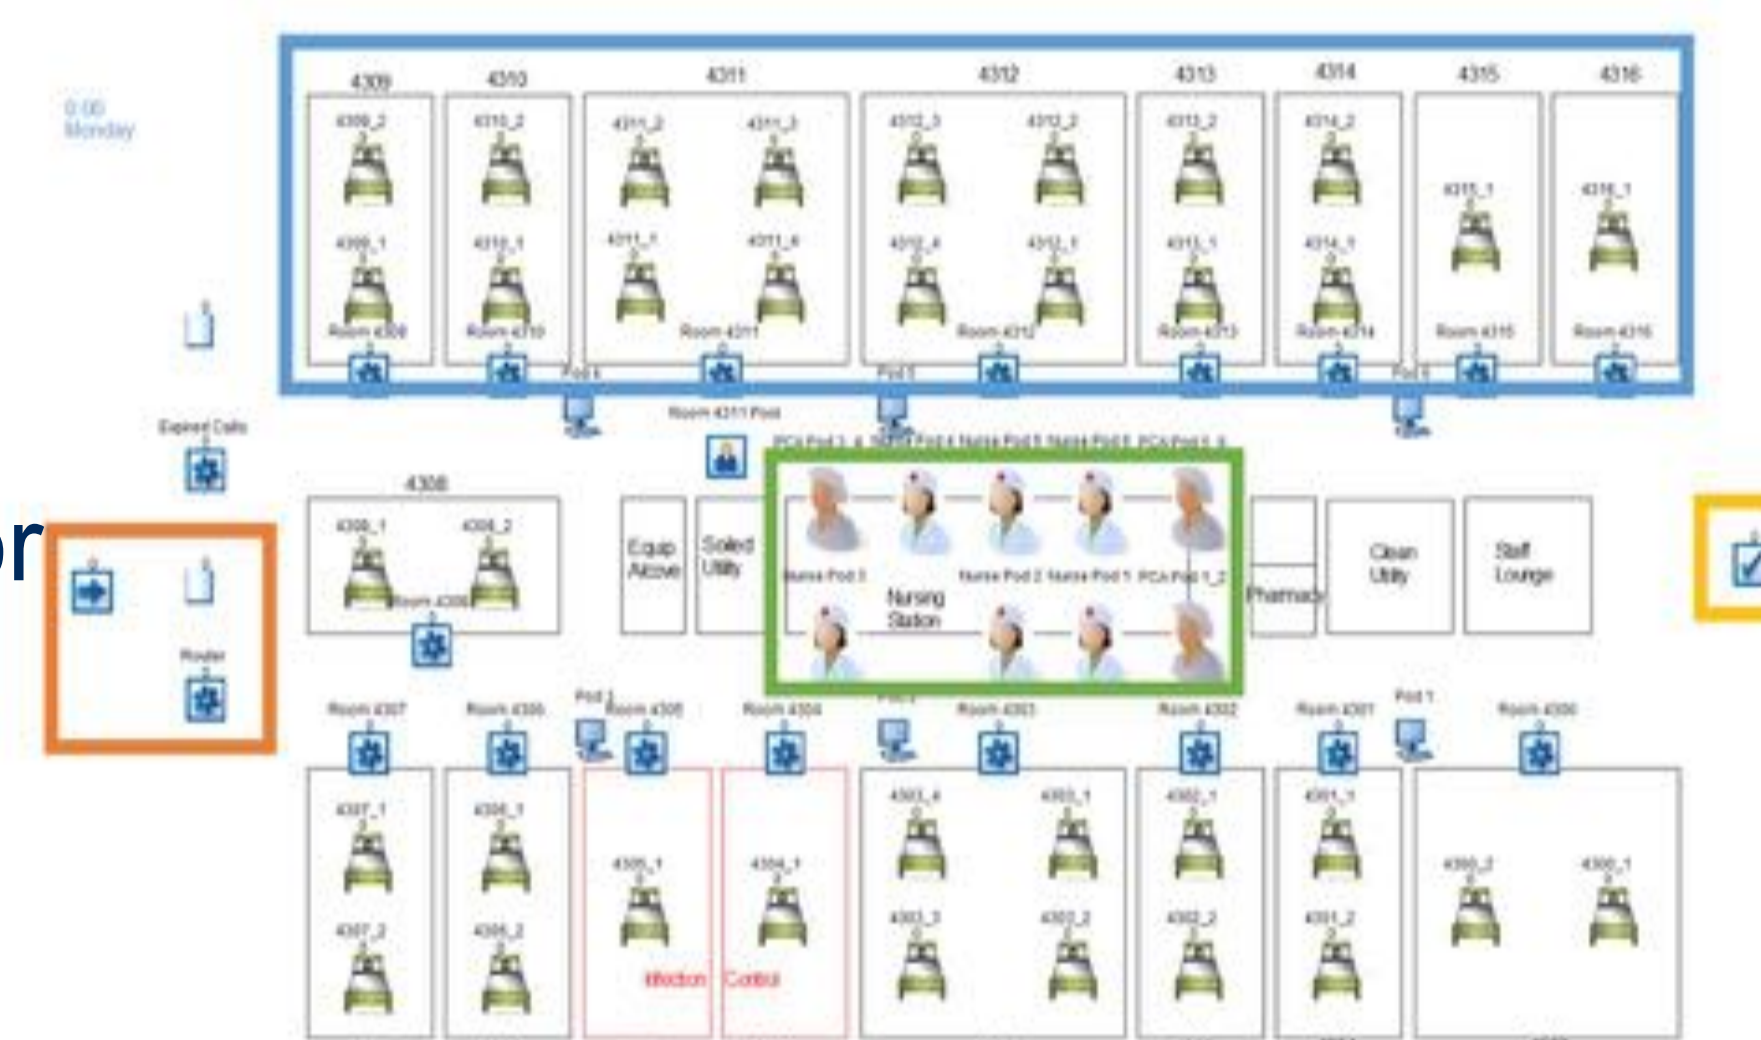

### RQ1) Evaluation:

- Interrupted Time series analysis to compare the pre and post intervention efficiency (length of stay) and patient safety (patient fall rate)
- Applied Rogers' Diffusion of Innovation Theory for nurse experience measurement
- Statistical analysis to measure Hand-Hygiene compliance rate and patient call response time

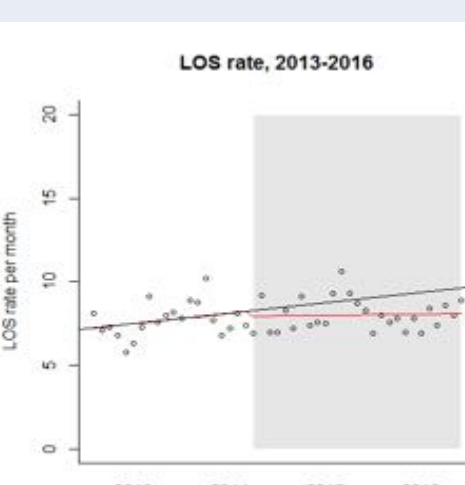

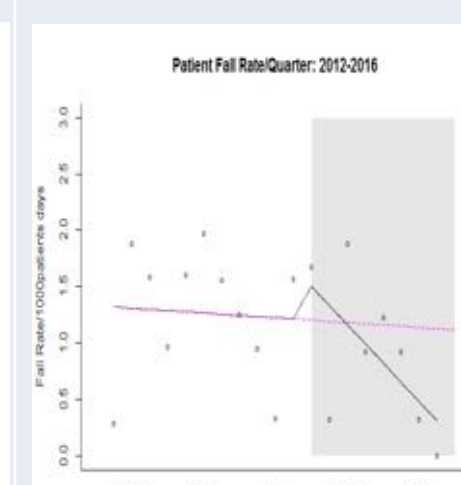

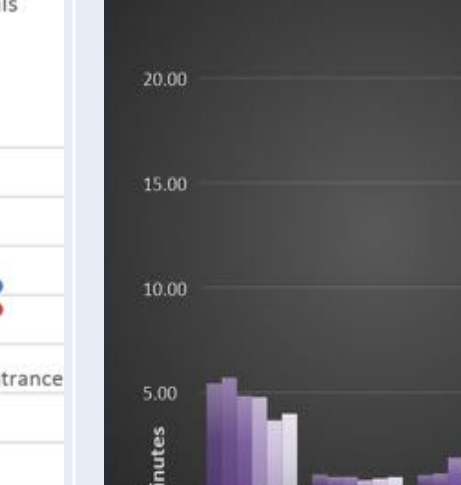

### RQ2) Future Improvements:

- Discrete Event Simulation (DES) for future call routing improvement scenarios

## Results – RQ1

| Efficiency  | Patient Safety  |   | Timeliness  | Staff Experience  |
|---|---|---|---|---|
| 1. Length of Stay (LOS)   | 2. Patient Falls  | 3. Hand-hygiene Compliance Rate   | 4. Patient Call Response Time   | 5. Interview with Nurses  |
| A non-significant incremental change post-intervention.                               | A non-significant incremental change post-intervention.                               | Increased up to 2015 followed by a decrease over 2015-2016.                           | Mixed trends in four main types of call response times.                               | Improvement in communication, direct patient care time and reduced number of patient falls. |
|  |  |  |  |   |

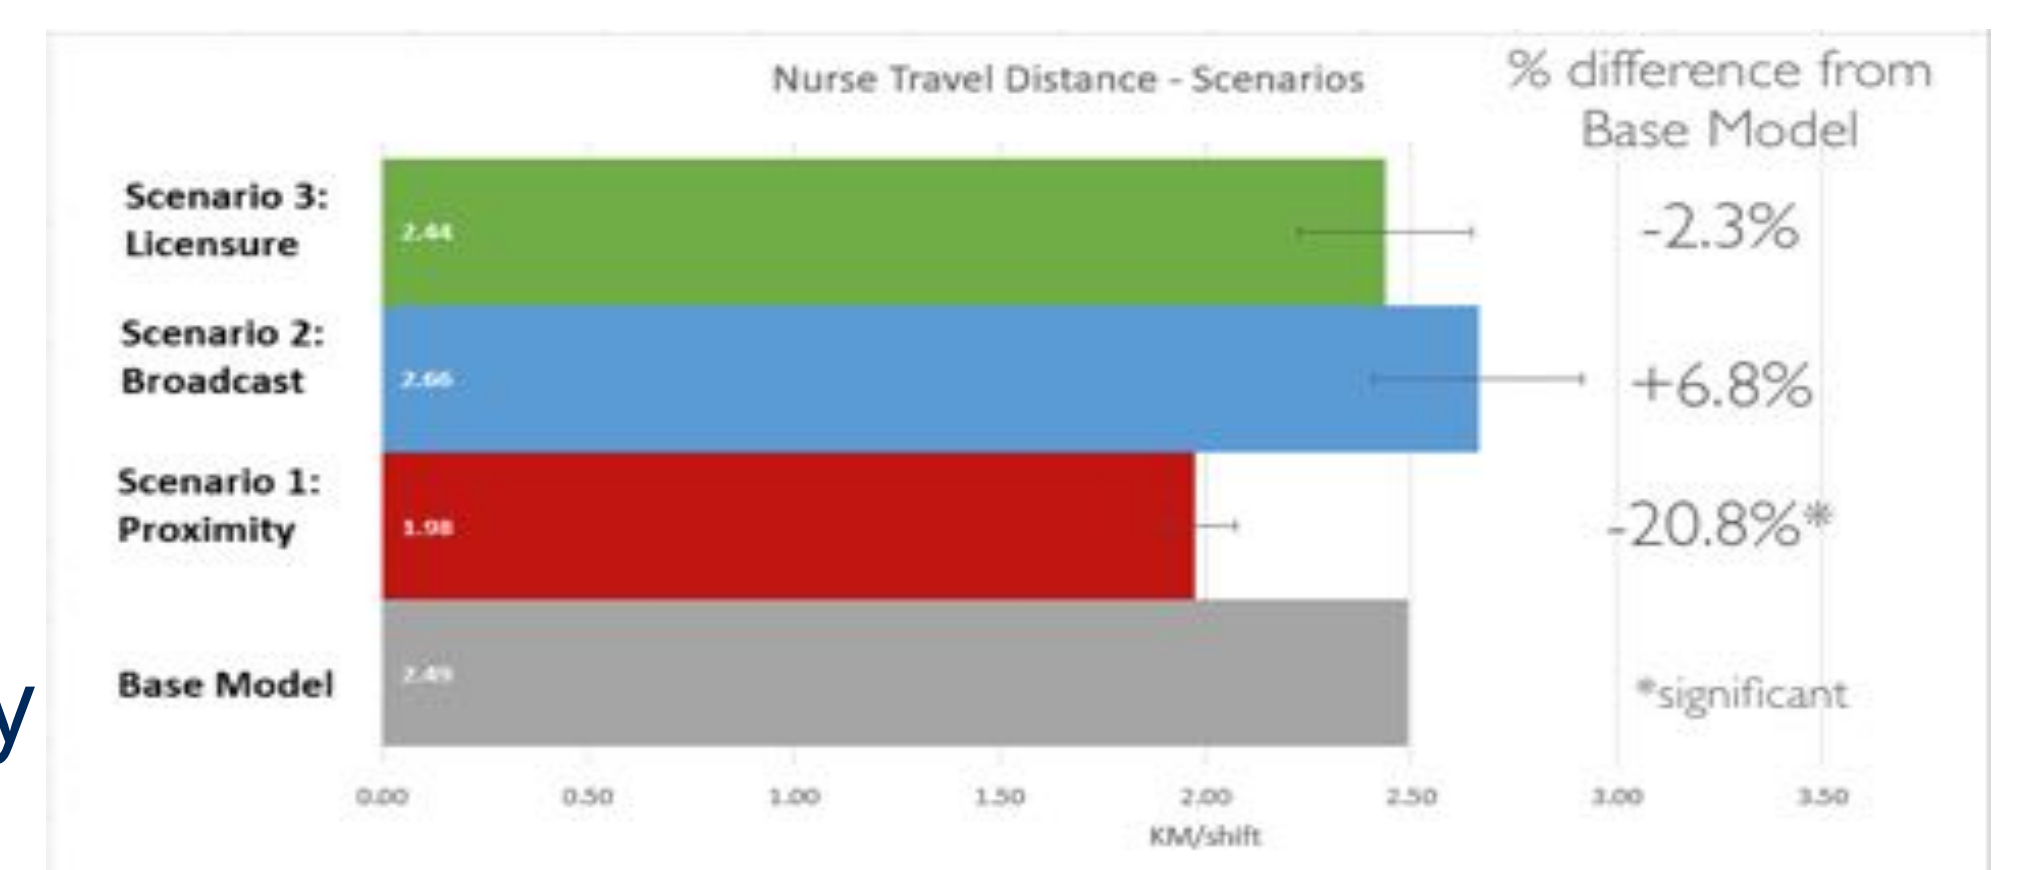

## Results – RQ2

Tested 3 alternative patient call routing scenarios:

- “Proximity” – nearest available nurse is sent call
- “Call Alternate Pod” (CAP) – call is sent to a less busy pod of nurses for them to assist
- “Call by Licensure” - calls are sent to relevant staff based on call type (e.g. bathroom calls sent to Personal Care Aids (PCAs)/Support Workers)

- Mean response times could be further reduced by ~6-18% depending on call strategy
- Nurse travel distance can be reduced by up to ~20%

|                        | Base | Scenario 1: Proximity | Scenario 2: Broadcast | Scenario 3: Licensure |
|------------------------|------|-----------------------|-----------------------|-----------------------|
| Mean (minutes)         | 2.49 | 1.98                  | 2.66                  | 2.44                  |
| % Difference from base | 0%   | -6.1%                 | -18.5%                | -11.8%                |

## Conclusion

1. Application of IoT at MH improved the efficiency (length of stay), patient safety (patient falls, HH-compliance rate), timeliness (patient call response time) and staff experiences
2. Further improvement in unit operations is possible through the use of alternative patient call routing strategies

## Acknowledgements

The authors would like to thank the OCE for funding this study, and Mackenzie Health for their collaboration on this project.
